

# RELATIONAL DATA MODEL

Fei Chiang (fchiang@mcmaster.ca)

15

## Describing Data: Data Models

16

- A data model is a collection of concepts for describing data.
- A schema is a description of a particular collection of data, using a given data model.
- The relational model of data is the most widely used model today.
  - ▢ Main concept: relation, basically a table with rows and columns.
  - ▢ Use tables to represent data and relationships
  - ▢ Every relation has a schema, which describes the columns, or attributes.

16

## Relational Model

17

- Proposed by Edgar. F. Codd in 1970 as a data model which strongly supports data independence.
- Made available in commercial DBMSs in 1981 -- it is not easy to implement data independence efficiently and reliably!
- It is based on (a variant of) the mathematical notion of relation.
- Relations are represented as tables.

17

## A relation is a table

18

Students

Relation Name	
Attribute Names	
ID	Name
2225555	Peter Jones
1234567	Amber Smith

Tuples (Records)

The set of permitted values for an attribute is called the attribute **domain**.  
 E.g.,  $\text{domain}(\text{ID}) = \{2225555, 1234567\}$ .

18

## Relational Data Model

19

- **Relation schema** = relation name and attribute list.
  - Optionally: types of attributes. For example:
    - *Students(id, name)*
    - *Students(id: string, name: string)*
- **Relation** = set of tuples conforming to schema
  - Example:
    - { (2225555, Peter Jones), (1234567, Amber Smith), ... }
- **Database** = set of relations.
- **Database schema** = set of all relation schemas in the database.

19

## Why Relations?

20

- Very simple model.
- **Often** matches how we think about data.
- Abstract model that underlies SQL, one of the most important database languages today.

20

## Relations are Unordered

21

- Order of tuples is irrelevant (tuples may be stored in an arbitrary order)
- E.g., *instructor* relation with unordered tuples

ID	name	dept_name	salary
22222	Einstein	Physics	95000
12121	Wu	Finance	90000
32343	El Said	History	60000
45565	Katz	Comp. Sci.	75000
98345	Kim	Elec. Eng.	80000
76766	Crick	Biology	72000
10101	Srinivasan	Comp. Sci.	65000
58583	Califieri	History	62000
83821	Brandt	Comp. Sci.	92000
15151	Mozart	Music	40000
33456	Gold	Physics	87000
76543	Singh	Finance	80000

21

## Database

22

- Information about an enterprise is broken up into parts
  - instructor*
  - student*
  - advisor*
- Bad design:
  - univ (instructor\_ID, name, dept\_name, salary, student\_id, ..)*
  - results in
    - repetition of information (e.g., two students have the same instructor)
    - the need for NULL values (e.g., represent a student with no instructor)
- Normalization theory deals with how to design “good” relational schemas

22

## Database Schemas in SQL

23

- SQL is primarily a query language, for getting information from a database.
- But SQL also includes a *data-definition* component for describing database schemas.

23

## Levels of Abstraction

- Many *views*, single *conceptual (logical) schema* and *physical schema*.

- ▣ Views describe how users see the data.
- ▣ Conceptual schema defines logical structure
- ▣ Physical schema describes the files and indexes used.

- Schemas are defined using DDL (data definition language);
- Data is modified/queried using DML (data manipulation language).

24

## Example: University Database

25

- Conceptual schema:
  - ▣ *Students*(sid: string, name: string, login: string, age: integer, gpa:real)
  - ▣ *Courses*(cid: string, cname:string, credits:integer)
  - ▣ *Enrolled*(sid:string, cid:string, grade:string)
- Physical schema:
  - ▣ Relations stored as unordered files.
  - ▣ Index on first column of Students.
- External Schema (View):
  - ▣ *Course\_info*(cid:string,enrollment:integer)

25

## Integrity Constraints

26

- An *integrity constraint* is a property that must be satisfied by all meaningful database instances.
- A constraint can be seen as a *predicate*; a database is *legal* if it satisfies all integrity constraints.
- Types of constraints
  - ▣ Intra-relational constraints: e.g., *domain constraints* and *tuple constraints*
  - ▣ Inter-relational constraints: most common is *referential constraint*

26

## Tuple and Domain Constraints

27

- A *tuple constraint* expresses conditions on the values of each tuple, independently of other tuples.
- E.g., **Net = Amount-Deductions**
- A *domain constraint* is a tuple constraint that involves a single attribute
- e.g., **(GPA ≤ 4.0) AND (GPA ≥ 0.0)**

27

## Unique Values for Tuples

28

RegNum	Surname	FirstName	BirthDate	DegreeProg
284328	Smith	Luigi	29/04/59	Computing
296328	Smith	John	29/04/59	Computing
587614	Smith	Lucy	01/05/61	Engineering
934856	Black	Lucy	01/05/61	Fine Art
965536	Black	Lucy	05/03/58	Fine Art

- Registration number identifies students, i.e., there is no pair of tuples with the same value for **RegNum**.
- Personal data could identify students as well, i.e., there is no pair of tuples with the same values for all of **Surname**, **FirstName**, **BirthDate**.

28

## Keys

29

- A *key* is a set of attributes that uniquely identifies tuples in a relation.
- More precisely:
  - ▢ A set of attributes K is a *superkey* for a relation r if r cannot contain two distinct tuples  $t_1$  and  $t_2$  such that  $t_1[K] = t_2[K]$ ;
  - ▢ K is a *(candidate) key* for r if K is a minimal superkey (that is, there exists no other superkey  $K'$  of r that is contained in K as proper subset, i.e.,  $K' \subset K$ )
